

# **Applied Numerical Methods for Civil Engineering**

CGN 3405 - 0002

## **Week 4: Introduction to Python Programming: Part II**

**Xinyu Chen**

Assistant Professor

University of Central Florida

## Quizzes Now!

- **Today's participation** (ungraded survey): Please check out

**"Class Participation Quiz 8"**

Time slot: **2:30PM – 3:00PM**

on Canvas.

## Python Functions

Why use functions?

- **Reusability:** Write once, use many times
- **Modularity:** Break code into manageable blocks
- **Abstraction:** Hide complexity behind simple interfaces
- **Testing & Debugging:** Isolate and test individual components

## Basic Function Syntax

```
1 def function_name(parameters):  
2     """Optional docstring"""  
3     # Function body  
4     return value # Optional
```

## Basic Function Syntax

### Engineering example.

- Definition of normal stress:

$$\sigma = \frac{F}{A}$$

```
1 def normal_stress(F, A):  
2     return F / A
```

where

- $F = 5000 \text{ N}$  (force)
- $A = 0.01 \text{ m}^2$  (area)

```
1 force = 5000    # N  
2 area = 0.01     # m^2  
3 stress = normal_stress(force, area)  
4 print('stress = {}'.format(stress))
```

## Lambda Functions

Quick, one-line functions:

- Example: Quadratic function

$$y = x^2$$

```
1 # Syntax: lambda arguments: expression
2 square = lambda x: x**2
3 print(square(5))      # 25
4
5 # Equivalent def function:
6 def square_func(x):
7     return x**2
8 print(square_func(5)) # 25
```

## Lambda Functions

### Engineering example.

- Definition of normal stress:

$$\sigma = \frac{F}{A}$$

```
1 stress_lam = lambda F, A: F / A
```

where

- $F = 5000 \text{ N}$  (force)
- $A = 0.01 \text{ m}^2$  (area)

```
1 force = 5000 # N
2 area = 0.01 # m^2
3 stress = stress_lam(force, area)
4 print('stress = {}'.format(stress))
```

## Lambda Functions

- Example:

$$g(r) = \frac{\pi r^2}{4}$$

```
1 import numpy as np
2
3 g = lambda r: np.pi * r**2 / 4
```

- Evaluate it for  $r = 1.5$  and  $r = 2.78$

```
1 print(g(1.5))
2 print(g(2.78))
```

## Multiple Returns

- Given  $ax^2 + bx + c = 0$  ( $a \neq 0$ ), the quadratic formula is

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

```

1 import numpy as np
2
3 def quad_formula(a, b, c):
4     term = np.sqrt(b**2 - 4*a*c)
5     x1 = (-b + term) / (2*a)
6     x2 = (-b - term) / (2*a)
7     return x1, x2

```

- Case study: Solve  $9x^2 + 3x - 2 = (3x - 1)(3x + 2) = 0$ .

```

1 a, b, c = 9, 3, -2
2 x1, x2 = quad_formula(a, b, c)
3 print(x1)
4 print(x2)

```

## Recursive Functions

### Functions that call themselves

- **Factorial of a non-negative integer**  $n$  is the product of all positive integers less than or equal to  $n$ :

$$n! = n \times (n - 1) \times (n - 2) \times \cdots \times 3 \times 2 \times 1$$
$$= \begin{cases} 1 & \text{if } n = 1 \\ n \times \underbrace{(n - 1)!}_{\text{factorial}} & \text{if } n > 1 \end{cases}$$

```
1 def factorial(n):  
2     f = 1  
3     for i in range(1, n + 1):  
4         f = f * i  
5     return f
```

- Toy example:  $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$

```
1 print(factorial(5))
```

## Recursive Functions

### Functions that call themselves

- **Factorial of a non-negative integer**  $n$  is the product of all positive integers less than or equal to  $n$ :

$$n! = n \times (n-1) \times (n-2) \times \cdots \times 3 \times 2 \times 1$$

$$= \begin{cases} 1 & \text{if } n = 1 \\ n \times \underbrace{(n-1)!}_{\text{factorial}} & \text{if } n > 1 \end{cases}$$

```

1 def factorial_r(n):
2     if n == 0:
3         return 1
4     else:
5         return n * factorial_r(n-1)

```

- Toy example:  $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$

```

1 print(factorial_r(5))

```

## Factorial with NumPy

- **Factorial of a non-negative integer**  $n$  is the product of all positive integers less than or equal to  $n$ :

$$n! = n \times (n - 1) \times (n - 2) \times \cdots \times 3 \times 2 \times 1$$

```
1 def factorial_numpy(n):
2     if n == 0:
3         return 1
4     else:
5         return np.prod(np.arange(1, n+1))
```

- Toy example:  $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$

```
1 print(factorial_numpy(5))
2 print(np.prod(np.arange(1, 6)))
```

## Factorial with NumPy

- **Factorial of a non-negative integer**  $n$  is the product of all positive integers less than or equal to  $n$ :

$$n! = n \times (n - 1) \times (n - 2) \times \cdots \times 3 \times 2 \times 1$$

```
1 def factorial_numpy(n):
2     if n == 0:
3         return 1
4     else:
5         return np.prod(np.arange(1, n+1))
```

- Toy example:  $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$

```
1 print(factorial_numpy(5))
2 print(np.prod(np.arange(1, 6)))
```

- Any other built-in function?

```
1 import math
2
3 print(math.factorial(5))
```

## Approximation for Sine Function

Taylor series expansion for  $\sin(x)$ :

- Formula

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \frac{x^9}{9!} - \frac{x^{11}}{11!} + \frac{x^{13}}{13!} - \frac{x^{15}}{15!} + \dots$$

- Denominator is factorial of odd numbers
- More terms = better approximation

## Approximation for Sine Function

Taylor series expansion for  $\sin(x)$ :

- Formula

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \frac{x^9}{9!} - \frac{x^{11}}{11!} + \frac{x^{13}}{13!} - \frac{x^{15}}{15!} + \dots$$

- Denominator is factorial of odd numbers
- More terms = better approximation
- Python programming:

$$\begin{aligned} \sin(x) &= \underbrace{\sum_{n=1}^{+\infty} (-1)^{n-1} \frac{x^{2n-1}}{(2n-1)!}}_{n \text{ starts from } 1} \\ &= \underbrace{\sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}}_{n \text{ starts from } 0 \text{ (Python!)}} \end{aligned}$$

## Approximation for Sine Function

- Python programming:

$$\sin(x) = \underbrace{\sum_{n=0}^{+\infty} (-1)^n \frac{x^{2n+1}}{(2n+1)!}}_{n \text{ starts from } 0 \text{ (Python!)}$$

```

1 import numpy as np
2
3 def sin_taylor(x, num_term):
4     result = 0
5     for n in range(num_term):
6         # Term index: 0, 1, 2, ... corresponds to x^1,
6             x^3, x^5, ...
7         exp = 2*n + 1
8         factorial = np.prod(np.arange(1, exp + 1))
9         result += ((-1) ** n) * (x ** exp) / factorial
10    return result

```

## Approximation for Sine Function

Test case:  $\sin(0.9)$

- Ground-truth value:

```
1 print(np.sin(0.9))           # 0.7833269096274834
```

- 1 term:

```
1 print(sin_taylor(0.9, 1))    # 0.9
```

## Approximation for Sine Function

Test case:  $\sin(0.9)$

- Ground-truth value:

```
1 print(np.sin(0.9))           # 0.7833269096274834
```

- 1 term:

```
1 print(sin_taylor(0.9, 1))   # 0.9
```

- 2 terms:

```
1 print(sin_taylor(0.9, 2))   # 0.7785
```

- 3 terms:

```
1 print(sin_taylor(0.9, 3))   # 0.78342075
```

- 4 terms:

```
1 print(sin_taylor(0.9, 4))   # 0.7833258498214286
```

- 5 terms:

```
1 print(sin_taylor(0.9, 5))   # 0.7833269174484375
```

## Quick Summary

### Monday's Class:

- Basic function syntax
- Lambda function
- Multiple returns
- Recursive functions
- Two examples: Factorial and Taylor series expansion for  $\sin(x)$
